Abstract: International organisations and academic communities have always shown a great interest in the evaluation and ranking of educational institutions. In recent years however, that interest has remarkably grown as the significance of higher educational institutions increases. For many parties involved, including students and their families, faculty members, funding organisations, and institutions themselves, such rankings are extremely important. To ensure neutrality and reflect the relative importance of each university, ranking techniques often incorporate a variety of indicator categories. These categories may include, but are not limited to, the impact and output of research activity, the teaching quality and learning environment, the variety of the student body internationally, and the reputation in the labour market. In addition to traditional ranking tools, clustering-based techniques can be used to classify universities based on their shared traits and assess their performance within each cluster. In this study, we investigate how universities from different geographical areas might be grouped into discrete groups according to their distinctive characteristics. We use a variety of clustering algorithms, each with unique properties—for this aim, and we compare the similarities between them. Finally, we investigate how university characteristics may affect the cluster formation.

Keywords: Clustering of Universities, Clustering, K-Means, GMM, Agglomerative, Fuzzy C-Means, Quacquarelli Symonds

1. Introduction

Finding a distinguished university is a critical step in securing a high-quality education, offering students a sturdy foundation of knowledge, skills, and credentials. Furthermore, it can lead to heightened career prospects post-graduation, as employers tend to favor graduates from prestigious universities, often translating into more enhanced job opportunities. These esteemed universities offer students the chance to participate in cutting-edge research, gain invaluable experiential insights, and cultivate essential skill sets crucial for their forthcoming endeavors.

Evaluating and ranking universities is a complex and multifaceted process that involves careful consideration of various indicators to ensure an objective and precise assessment. Leading ranking organizations, such as the Academic Ranking of World Universities (ARWU) [1], Quacquarelli Symonds (QS) [2], and Times Higher Education World University Rankings (THE) [3], employ sophisticated algorithms to evaluate universities based on a wide range of factors, including academic reputation, faculty-student ratio, academic citations, and international diversity. Each indicator is assigned a specific weight to reflect its relative importance in the university evaluation process. According to [4], an examination of these indicators reveals the following:

• The low similarity of indicators across ranking lists implies that organizations primarily rely on distinct sets of criteria when assessing universities.

- The weight assigned to indicate the significance of an indicator can vary across different ranking lists.
- The research production and impact-related indicators are similar among ranking lists.

University rankings not only aid students in making informed decisions, but also incentivize universities to enhance their performance in critical domains like research, teaching, and internationalization, all of which are essential to their stakeholders. While these rankings offer significant benefits, they are not without limitations, including the following:

- **Subjectivity**: The choice of indicators and their associated weights may rely on subjective and contentious criteria, resulting in rankings that do not accurately reflect the genuine capabilities and performance of universities.
- Narrow Focus: The indicators employed in ranking systems might fall short of encompassing the entire spectrum of activities and outputs of universities, potentially resulting in a limited and partial assessment of their performance. For instance, rankings primarily centered around research productivity may not adequately gauge the quality of teaching or the broader impact of universities on their local communities.
- **Incentive Distortion**: Ranking systems can incentivize universities to prioritize specific activities over others, potentially distorting their original missions and objectives.
- Lack of Transparency: The lack of transparency in the methodology and data sources
 employed by ranking organizations poses a challenge for universities to pinpoint and
 address areas for improvement. Additionally, this opacity may foster skepticism and
 mistrust among stakeholders towards the reliability of the rankings.

Employing a clustering method to group universities based on particular characteristics or criteria can provide individuals with a more holistic insight into each institution's strengths and weaknesses, thus aiding them in making informed decisions about their educational or professional paths. This approach may be preferable to a straightforward ranking of universities from top to bottom for several compelling reasons, such as:

- A limitation of criteria: Ranking methodologies often rely on a narrow set of criteria for assessing university performance, yet certain universities excel in diverse domains of expertise. Consequently, employing clustering methods can highlight their individual strengths and areas of excellence.
- Diverse needs: Every individual harbors distinct priorities when it comes to selecting
 a university, encompassing factors like expenses, geographic location, and available
 academic programs.
- Avoiding Stigma: Establishing a ranking hierarchy where universities are sorted from
 the best to the least can result in the marginalization of lower-ranked institutions. To
 alleviate this effect and promote a more constructive and inclusive view of universities,
 clustering them based on specific attributes or areas of expertise can be a valuable
 alternative.

The remainder of the article is organized as follows: In Section 2, we review other related studies, while Section 3 presents the dataset and the data pre-processing phase. Section 4 presents the methodology, and finally, Section 5 concludes our study.

2. Related Work

Clustering is a machine learning technique that belongs to the category of unsupervised learning and aims to group related objects together into distinct clusters. There are several different types of clustering, each with its own benefits and drawbacks. Some of the types of clustering are:

 Hierarchical: Utilizing this methodology, clusters are structured within a dendritic, tree-like arrangement, in which each smaller cluster serves as a subset of a more comprehensive cluster. Two fundamental modes of hierarchical clustering are evident: agglomerative [5] and divisive [6]. Within the agglomerative clustering technique,

each data point originates within its own distinct cluster, culminating in the eventual amalgamation of all clusters into a unified entity. Conversely, the divisive clustering method commences with all data points situated within a solitary cluster, subsequently undergoing incremental partitioning into smaller clusters through the algorithm.

- **K-Means**: One widely employed clustering method is K-means clustering [7]. In this technique, the dataset is partitioned into *K* clusters, where *K* is a modifiable parameter. The objective is to minimize the total sum of squared distances between each data point and its designated cluster center.
- Fuzzy Clustering: This approach enables data points to exhibit multiple degrees of membership across multiple clusters. Among the field, Fuzzy C-Means (FCM) clustering [8] stands as the most widely utilized algorithm for fuzzy clustering.
- Density-Based: The density-based clustering technique involves the grouping of data
 points that are in close proximity within high-density regions while being separated
 by regions of lower density. Among these methods, DBSCAN [9], which stands for
 "Density-Based Spatial Clustering of Applications with Noise", is the most widely
 recognized density-based clustering algorithm.
- Model-Based This methodology posits a mixture of probability distributions as the origin of the data points. Among model-based clustering techniques, the Gaussian Mixture Models (GMM) algorithm [10] stands as the most prevalent and widely employed approach.

Considerable research has been undertaken in the field of evaluating and ranking academic institutions, spanning universities, departments, and diverse academic domains.

A renowned technique employed for the evaluation of university rankings is rank fusion [11]. Rank fusion, also referred to as meta-ranking, constitutes a procedure for amalgamating the outcomes of multiple university rankings, which include assessments based on multiple factors and criteria, thereby yielding a more encompassing and dependable overall ranking. The process of rank fusion entails the normalization of diverse rankings and their amalgamation through a weighted averaging mechanism, wherein the assigned weights signify the significance attributed to each respective ranking.

In contrast to individual ranking systems, the process of rank fusion presents several advantages. It fosters a greater degree of stability and dependability in the rating system, diminishing the impact of outliers or inaccuracies within individual rankings. Additionally, it possesses the capacity to consider a broader spectrum of factors or perspectives, thereby furnishing a more comprehensive assessment of the performance or quality of the ranked entities. However, it is imperative to exercise caution when employing rank fusion, as the weights applied to amalgamate the rankings may carry a degree of subjectivity or bias.

A useful method for ranking universities is the Borda Count method [12]. The Borda Count method is a single-winner, voting-based technique for aggregating and consolidating rankings from different sources or criteria. In this method, each university is assigned a score in each individual ranking, typically based on its position in that ranking. The scores are then summed across all rankings, and universities are ranked based on their total scores. The higher a university ranks in an individual ranking, the more points it receives. The Borda Count allows for the integration of diverse indicators into a single composite ranking. It's particularly useful when dealing with university rankings from various organizations, as it provides a way to balance and combine these rankings to create a unified assessment of university performance that reflects the collective preferences of the rankings.

There exists a multitude of scholarly investigations concerning the ranking of universities, drawing inspiration from conventional methodologies such as Data Envelopment Analysis (DEA) [13,14], multicriteria sorting [15], the application of the Pareto Frontier [16], as well as the aforementioned rank fusion technique. Nevertheless, it is important to acknowledge that each university ranking entity may adopt a distinct ranking framework or devise proprietary methodologies to appraise the performance of individual universities, thereby yielding divergent ranking lists.

For our study, we relied on [17], although [18] is very similar to our analysis. In [17], the authors clustered the top 500 universities from the National Taiwan University (NTU) ranking list. The NTU ranking list is based on eight validated research performance indicators, categorized into three main categories, each with a corresponding weight:

- Research productivity 25%
- Research impact 35%
- Research excellence 40%

The outcomes of their clustering experiments, involving 12 and 43 clusters, utilizing the DBSCAN, EM (Expectation-Maximization) [19], and K-Means algorithms, demonstrated a strong similarity to the ranking provided by the NTU ranking list. This similarity was notably pronounced with the EM and K-Means algorithms, while the DBSCAN algorithm did not yield comparable results. Within the 12 and 43 clusters derived from their analysis, a singleton cluster emerged at the top, containing a single university recognized for its exceptional performance. As a result, they concluded that K-Means stands out as the most suitable algorithm for university clustering.

In the study [18], the dataset from Quacquarelli Symonds (QS) for the year 2022 served as the basis for clustering and analysis. The author employed six score indicators, elaborated in Section 3, and opted for the Gaussian Mixture Model (GMM) as the primary clustering algorithm. Differing from the eight research-oriented indicators employed in [17], the QS indicators encompass a broader spectrum of criteria for evaluating university performance. The determination of the optimal number of clusters, set at four, was accomplished using Akaike's Information Criteria (AIC) [20] and Bayesian Information Criteria (BIC) [21]. In contrast to QS's existing ranking system, the study's findings introduced a novel classification scheme for universities, where each cluster portrayed universities in a manner distinct from their assigned rankings in the QS list.

In [22], the authors classified the top 500 universities into 21 types according to their disciplinary characteristics, using data from the Institute of Higher Education, Shanghai Jiao Tong University. The indicators used for the classification are the percentage of publications in six broad disciplinary areas:

- 1. Arts/Humanities & Social Sciences
- 2. Natural Sciences & Mathematics
- 3. Engineering/Technology & Computer Sciences
- 4. Life Sciences
- 5. Clinical Medicine
- 6. Interdisciplinary & Multidisciplinary Sciences

Universities were categorized based on their focus, priority, and orientation with specific disciplinary groups. Those universities that did not fall into any of the aforementioned categories were designated as "balanced". An examination was conducted to assess the distribution of various types of universities across nations and ranking systems. In the clustering procedure, a customized algorithm was employed, utilizing the Squared Euclidean Distance as the similarity metric.

There are other notable studies related to our work of clustering universities, such as those in [23–26]. In [23], the object of research is the internal structure of management in universities, it's relationship to rating, and the clustering of universities in the Republic of Kazakhstan in order to determine the effectiveness of management. The authors consider three clustering models, each of which presents intriguing results regarding the clustering parameters and their values. In [24], to enable a more suitable and fair comparison of knowledge exchange performance among English institutions, a cluster analysis is sought to identify groups of universities based on their structural characteristics that shape knowledge sharing possibilities and challenges. The study also recognizes the criticality of diverse higher educational institutions and the difficulties that arise from clustering them. In [25], the study highlights the universities located in countries that host 90% of the top ranked universities in Latin America by presenting the findings of a descriptive

analysis based on clusters of 85 Latin American universities found in the top 50 positions of the ARWU, SIR Scimago, QS, and Webometrics rankings. For the purposes of performing the descriptive statistical analysis, clusters were constructed by taking into account the frequency of the presence of universities in the top 50 of the four rankings, their location, and the country they belong to. In [26], the purpose of the study was to classify Korean universities according to their research performance, and validate the classifications by comparing their research performance to those that are located in the U.S. As compared to U.S peers, Korean universities' research performance was comparable. Furthermore, the study revealed that the classification outcomes produced by the performance-based method were comparable to those of conventional classifications that used predetermined criteria. However, the above studies are limited only to national or regional data.

Compared to the analyses conducted in studies [17], [18] and [22], our study employed K-Means, GMM, Agglomerative, and Fuzzy C-Means algorithms to offer a more comprehensive and nuanced perspective on the dataset. This approach aimed to unveil diverse patterns and structures that may remain concealed when relying on a single algorithm. To ensure a fair and equitable university clustering process, we expanded upon the six indicators utilized in study [18] by incorporating three additional indicators sourced from the ranking list, as detailed in Section 3. In contrast to the methodologies applied in studies [17] and [22], which predominantly incorporated research-focused indicators, our approach encompassed a broader spectrum of indicators for evaluating university performance. Despite Fuzzy C-Means calculating the probability of a university belonging to multiple clusters, our algorithm ultimately assigned each university to a single cluster.

3. Dataset and Data Pre-Processing

3.1. Dataset

For the purposes of this research, we acquired a dataset from the official website of the Quacquarelli Symonds (QS) for the year 2023. In the dataset, there are over 1400 universities from all over the world, including universities from diverse locations in Europe, Asia, and North America. We selected this particular dataset due to the presence of diverse indicators used for the assessment of university performance, in contrast to other university rankings that primarily rely on bibliographic-related metrics.

Totally, there are 27 columns in the dataset, but according to the QS ranking, each university is ranked and assessed using only six columns/indicators named:

- 1. **Academic Reputation** (ar score): Evaluates the teaching and research quality of the university.
- 2. **Employer Reputation** (er score): Evaluates how competent, innovative, and effective students and graduates are for the employment market.
- 3. **Faculty/student ratio** (fsr score): Evaluates how universities provide students with meaningful access to faculty staff.
- 4. **Citations per faculty** (cpf score): Evaluates the total number of academic citations about the papers published in the last five years.
- 5. **International student ratio** (isr score): Evaluates the ability of a university to attract foreign students.
- 6. **International faculty ratio** (ifr score): Evaluates the ability of a university to attract foreign faculty staff.

The above indicators, each in turn, get a percentage of 40%, 10%, 20%, 20%, 5%, and 5% of the total score.

In our analysis, we include three additional indicators named:

- 1. **Size**: The total number of full-time degree-seeking students.
- 2. **Focus**: The broad subject areas of each university, e.g Arts, Humanities, Engineering and Technology, Natural Sciences etc.
- 3. **Age Band**: The age of each university.

The selection of the three supplementary indicators is premised on their ability to facilitate the categorization of universities according to their respective values Table 1. This enables the establishment of distinct and equitable rankings among the institutions, thus providing a more comprehensive evaluation of their performance across multiple dimensions. Each of the three indicators captures a percentage of the total number of universities. All the above indicators have been selected to be applicable to all universities regardless of geographical area.

Table 1. Size, Focus, Age Band

	Size	Students	Perc. (%)
XL	Extra Large	More than 30.000	23.8
L	Large	≥ 12.000	46.6
M	Medium	≥ 5.000	23.8
S	Small	Fewer than 5.000	5.8
	Focus	Faculty Area	
FC	Full comprehensive	5 faculty areas & medical school	41.6
CO	Comprehensive	5 faculty areas	32.5
FO	Focused	3 or 4 faculty areas	22.0
SP	Specialist	2 or fewer faculty areas	3.9
	Classification	Age	
5	Historic	100 years old and more	37.5
4	Mature	50-99 years old	34.4
3	Established	25-49 years old	20.4
2	Young	10-24 years old	6.7
1	New	Less than 10 years old	0.9

3.2. Data Pre-Processing

Following the description of the indicators used in our analysis, it is important to undertake certain data pre-processing steps as a necessary precursor to the clustering process. As an initial step, the exclusion of universities with missing data in any of the aforementioned nine indicators is essential to ensure equitable evaluation. Subsequently, categorical string values within the "size" and "focus" indicators are mapped into categorical numerical values spanning from 0 to 100. This conversion is conducted in order for the clustering algorithms to function properly, as they receive only numerical values. Lastly, to scrutinize the correlation among the indicators, whether categorical or continuous, we employ the Spearman rank correlation coefficient [27]. The resulting correlation matrix for the nine indicators is provided in Table 2.

Upon scrutinizing the aforementioned tables, several pertinent observations can be deduced, contributing to the formulation of meaningful conclusions in the context of the present research. The academic and employer reputation indicators have a relatively strong correlation with most of the other indicators and especially with one another, implying that, as the academic reputation of a university increases, employers are more likely to hire students who graduated from that university. Furthermore, a strong correlation is observed in the relationship between the number of international students and the presence of foreign faculty staff. This outcome aligns with expectations, as a university's acceptance of a substantial number of international students logically corresponds with the recruitment of foreign faculty members. Another strong and obvious correlation emerges between a university's academic reputation and the quantity of citations per faculty. This alignment is unsurprising, given that a higher volume of citations stemming from a school's research activities naturally increases the university's overall academic standing. Noteworthy

Table 2. Spearman rank correlation matrix for the nine indicators

observations can be made regarding the size, focus, and age band indicators. It is apparent that the size of a university influences its focus, and vice versa, but does not significantly impact the age of the university. Therefore, the presence of an extensive array of faculty areas in a university does not necessarily imply an older age but rather suggests a relatively larger student population. Additionally, upon analyzing their correlation with the other continuous indicators, it is clear that the size, age, and broad subject areas do not exert a significant influence on a university's overall performance.

Having established the relative significance of specific indicators within our cluster analysis, our subsequent action entailed the implementation of two techniques prior to the normalization process:

- 1. We applied custom weights to the indicators, which were derived from the initial weight assignments provided by the QS.
- 2. We excluded all the weights from the normalization process in order to have a more balanced and fair clustering.

Subsequently, we normalized the indicator values to fit within the 0 - 1 range using the MinMaxScaler algorithm:

$$x_{\text{scaled}} = \frac{x - x_{\min}}{x_{\max} - x_{\min}}$$

Each technique was used once per experimentation cycle. One experimentation cycle involves the following steps:

- 1. Normalizing the data using one of the aforementioned techniques.
- 2. Clustering the data.
- 3. Computing the pairwise similarity between all combinations of clustering algorithms using the Rand Index (RI) [28].

By calculating the similarity between a pair of clustering algorithms, we gain insights into the degree of proximity between them. However, our objective is to compare the ranking list generated through the amalgamation of clusters produced by a clustering algorithm, with the QS ranking list. Details of how a ranking list is produced from the clustering algorithms are discussed in Section 4. To facilitate this comparison, we created distinct clusters to represent the QS ranking list, separate from those produced by the algorithms. The size of these clusters will correspond to the size of the clusters generated by the clustering algorithms. Consequently, the members of the new clusters, which are the universities, will be organized to match the order of universities as presented in the QS ranking list. For example, if the first cluster has a size of 100, that cluster will encompass

the first one hundred universities from the QS ranking list. The second cluster, irrespective of its size, will encompass the consecutive universities following the top one hundred universities from the first cluster. This approach allows us to essentially compare the QS ranking list, which is represented by these new clusters, with the rankings produced by the clustering algorithms.

4. Methodology

The clustering algorithms that were used for this analysis are the following:

- 1. **K-Means** K-means can be a useful algorithm for university clustering in certain situations, particularly when simplicity, efficiency, and intuitive results are important.
- 2. **GMM** Assuming the data can be described as a combination of Gaussian distributions, GMM can be a valuable technique for university clustering. It can offer adaptability, interpretability, and identification of universities with distant indicator values. It can also aid in improving comprehension and analysis of the performance of various university groups.
- 3. **Agglomerative** Agglomerative clustering can be used when a hierarchy of clusters is needed, or when flexibility and interpretability are important. However, it may not be the best choice for all situations, particularly when the underlying data has complex relationships or non-linear distributions.
- 4. **Fuzzy C-Means** Fuzzy C-Means is a useful algorithm for university clustering due to its ability to allow each university to belong to multiple clusters, with varying degrees of membership. Practically, for our case scenario, a university can be assigned to a specific cluster but it can also possess a high probability of being a member of a neighbouring cluster. Thus, it helps us to make a more nuanced analysis of the performance and characteristics of different groups of universities.

To find the optimal number of clusters using the nine indicators we used:

- 1. The elbow method for a maximum of 30 clusters using the K-Means algorithm to calculate the sum of squared distances from each point to its assigned center.
- 2. The Akaike Information Criterion (AIC) and the Bayesian Information Criterion (BIC) for a maximum of 30 clusters. The maximum number of clusters was chosen arbitrarily. Since AIC and BIC are both statistical measures used for model selection and comparison, we used the GMM algorithm for these measures.

By applying the elbow method, the graph in fig. 1 came up. By taking a closer look at the graph, it is apparent that the elbow method does not work well because, as we will see later on, the data is not very clustered. As a result, there is a smooth curve and the optimal value of *K* is unclear, thus making this method unfit for use.

Using the AIC and BIC measures we came up with the graph that is shown in fig. 2. The number of clusters for the minimum value of BIC is seven which is identical to the results of the EM algorithm. The number of clusters for the minimum value of AIC is approximately 29 but we used 24, as the difference between the AIC value of 29 and 24 clusters is quite small. In order to visualize the clusters, we used the Multidimensional Scaling (MDS) algorithm [29] to reduce the initial dimensions of the data to two.

The clusters are *ordered* according to the mean value of each cluster (CM). The mean value of a cluster is calculated as follows:

$$CM = \frac{\sum_{j=1}^{cluster\, size} \frac{\sum_{i=1}^{9} indicator_{j,i}}{9}}{cluster\, size}$$

We calculate a university's overall performance by summing up its individual indicator values and then dividing the total by nine, the number of indicators, to derive the mean score. Next, by aggregating the means of all universities within a cluster and dividing this sum by the cluster's size, we obtain the cluster's mean score. The top universities are therefore found in the red cluster, followed by the next best performing universities, which

358

359

361

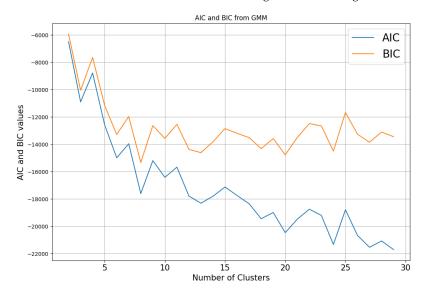

Figure 2. AIC & BIC values for a maximum of 30 clusters and a minimum of two.

are found in the yellow and light blue clusters, according to the results. This methodology generates a cluster ranking that subsequently reflects the ranking of universities within each respective cluster.

The clustering results for seven clusters and nine indicators without weights are shown in fig. 3. The sizes of each cluster for every algorithm are shown in table 3. Table 4 presents the similarity between every pair of algorithms.

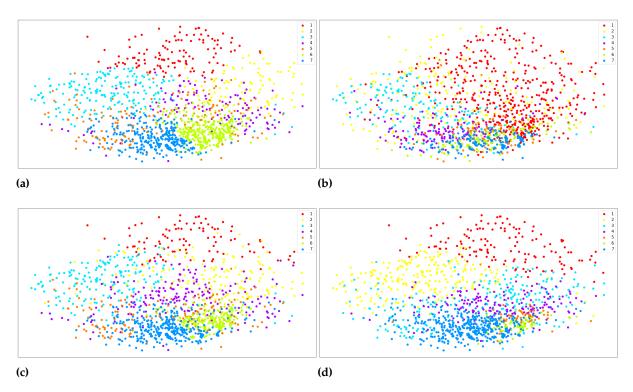

Figure 3. Visualization for seven clusters without weights. (a) K-Means (b) GMM (c) Agglomerative (d) Fuzzy C-Means

Agg	99	138	166	183	145	220	357
Fuzzy	138	221	214	161	62	81	431

Table 4. Rand Index for seven clusters without weights

	KM	GMM	Agg	Fuzzy	QS
KM	1				
GMM	0.72717	1			
Agg	0.86629	0.729395	1		
Fuzzy	0.831397	0.716887	0.819637	1	
QS	0.775647	0.753169	0.78335	0.784693	1

By visualizing the results of the clustering algorithms and calculating the Rand Index (see table 4), we can make a few observations. First of all, the cluster with the highest mean (the red cluster), for every algorithm, has a very low density. That is to be expected given that universities in that cluster tend to have diverse values for their indicators, whereas universities in clusters with lower means tend to have similar values for these indicators. Thus, clusters with a lower mean have a higher density.

It's important to note that the clusters exhibit overlap, meaning that universities belonging to one cluster may appear in others. This overlap is a result of two key factors. Firstly, the clustering process relies on nine distinct indicators, while the visualization phase reduces

these indicators to just two dimensions. This dimensionality reduction can lead to errors in accurately representing the data. Secondly, the differentiation between the cluster members of a clustering algorithm and the QS clusters contributes to the observed overlap. For the sake of comparison, we assume that the cluster members of a clustering algorithm mirror those of the QS clusters (the clusters created to compare the QS ranking list to the ranking list produced by the clustering algorithms). This assumption implies that, regardless of their size, each cluster of a clustering algorithm will encompass the same members (universities) as its corresponding counterpart of the QS clusters. In practice, however, the cluster members of a clustering algorithm often differ from those of the QS clusters. In other words, a university may find itself within a cluster featuring a lower mean, while according to the clustering of QS, it should have been placed in a cluster with the highest mean, or vice versa. As a result, some universities may appear in the wrong clusters, according to the QS.

In order to compare the clusters derived from the clustering methods with those of the QS, we select the algorithm that demonstrates the highest similarity to the QS, as defined by the Rand Index. In an ideal scenario, as previously mentioned, the clusters should encompass universities in the same order as they appear in the QS clusters. However, our analysis reveals situations where universities that were intended for one cluster are, in fact, assigned to a different one.

Table 5 illustrates the difference among the cluster members of Fuzzy C-Means and QS, and Fig. 4 provides a visual representation corresponding to the findings presented in table 5. The Cluster Differentiation (CD) row in table 5 enumerates the difference between the cluster members of Fuzzy C-Means and QS clusters. For example, the first cluster has a CD of 15, implying that there are 15 universities in the first cluster of QS that are not present in the first Fuzzy C-Means cluster. In fig. 4, the university nodes are delineated by two colors. The left-color designates the cluster to which a university belongs according to the results of fuzzy C-Means, while the right-color designates the cluster a university is expected to be a part of based on the clustering of QS. The complete/detailed list of clusters can be found in table 16.

In terms of university distribution within the clusters, the K-Means algorithm and the Agglomerative method exhibit considerable similarity. The outcomes of one align closely with the results of the other, and their Rand Index demonstrates a relatively high level of agreement compared to other algorithms. Fuzzy C-Means shares similarities with K-Means and Agglomerative methods, but upon closer examination through the graph and size table, it becomes evident that Clusters 5 and 6 contain significantly fewer universities than their counterparts in the other two methods. Interestingly, the number of universities in the final cluster of Fuzzy C-Means exceeds those in K-Means and Agglomerative by a considerable margin. GMM stands out distinctly from all other algorithms, characterized by an exceptionally large size of the first cluster, and notably, the smallest size of the last cluster in comparison to corresponding clusters in the other algorithms. Furthermore, GMM reveals that a significant number of universities from the top clusters are intermixed with universities from clusters of lower means to a degree not observed in the other clusters.

The clustering results for 24 clusters and nine indicators without weights are shown in fig. 5. According to table 6, the Rand Index between every pair of algorithms has significantly increased and the results are now closer to QS. Considering that, we can conclude that as we increase the number of clusters, the similarity between a clustering algorithm and QS increases. Moreover, table 7 presents the cluster sizes, while table 8 lists the differentiation between cluster members of Agglomerative and QS clusters for 24 clusters without weights.

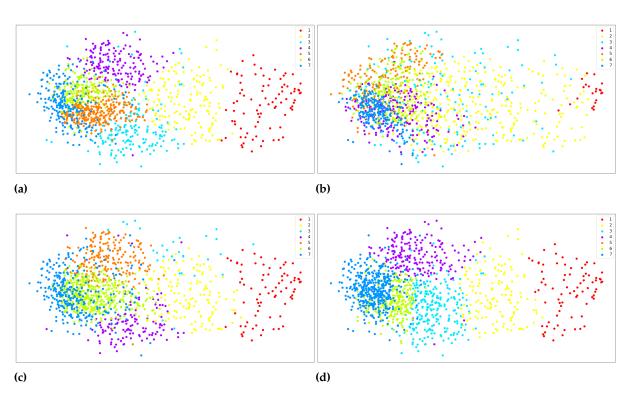

Figure 7. Visualization for seven clusters and nine indicators multiplied with weights. (a) K-Means (b) GMM (c) Agglomerative (d) Fuzzy C-Means

 Table 9. Rand Index for seven clusters with weights

	KM	GMM	Agg	Fuzzy	QS
KM	1				
GMM	0.753332	1			
Agg	0.843404	0.71782	1		
Fuzzy	0.823589	0.729534	0.774022	1	
QS	0.783518	0.768862	0.739359	0.7783	1

The Rand Index (table 9) between the weighted clustering, utilizing 9 indicators multiplied by weights, and the unweighted clustering shows a relatively modest change. Specifically, we observe a slight increase in the similarity between Fuzzy C-Means algorithm and Agglomerative, which results in an improvement in the similarity between Agglomerative and QS. Kmeans exhibits a higher similarity with QS.

443

446

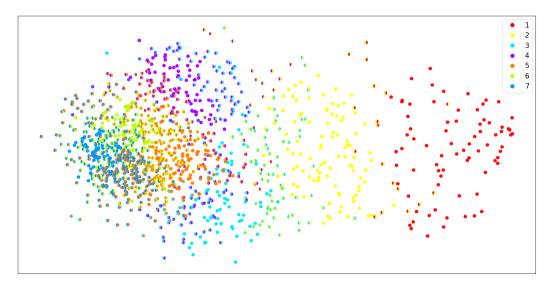

448

In terms of the configuration and size of the clusters (table 10), the graphs reveal that clusters generated by the K-Means, Agglomerative, and Fuzzy C-Means algorithms are more distinctly separated in the weighted approach, making it easier to discern the distribution of universities. However, this improvement does not extend to the GMM algorithm, where clusters remain mixed with one another. The differentiation between

0.1	0.1	0.1	0.25	0.1	0.125	0.125	0.05	0.05

In the case of clustering with 24 clusters in fig. 9, there are no noteworthy observations regarding the K-Means and Agglomerative methods. In the case of Fuzzy C-Means, it is notable that results are provided for only 20 clusters (table 13). This is due to the presence of 4 clusters with zero universities. This is not surprising, given that there are already two clusters that have only one university. The specific identity of these clusters with zero universities does not carry particular significance, as universities are generally assigned to

454

455

456

a cluster before the calculation of cluster means. The calculation of the mean value of each cluster is the key determinant of a cluster's significance, and in this context, clusters with zero universities are excluded from that process.

According to table 15, kmeans demonstrates a higher similarity with QS for 24 clusters with weights. Finally, the differentiation between cluster members of kmeans and QS clusters for 24 clusters with weights is presented in table 14 and visualised in fig. 10.

5. Conclusion

Rankings offer a clear and straightforward way to compare universities, while clustering provides a more nuanced understanding of the diversity and similarities within the higher education landscape. Instead of a strict numerical ranking, clustering provides a more comprehensive view by highlighting similarities and differences between groups of universities, allowing for better comparisons and assessments. Clustering analysis introduces a dynamic aspect to rankings, highlighting that institutions can move between clusters based on their performance over time. Moreover, grouping universities may impact their reputation positively or negatively, depending on the cluster they belong to. Institutions in higher-ranked clusters may experience an improvement in their global reputation, attracting more students, faculty, and research collaborations.

In this article, we conducted a thorough analysis of university ranking data and concluded that clustering methods can be applied to group institutions with similar characteristics and provide a ranking between different groups. The latter is achieved by ordering clusters based on the performance of institutions within them. When examining the distribution of institutions within each cluster, discernible differences emerge among clusters generated through different algorithms, varied cluster numbers, or the inclusion of adjusted weights,

477

480

481

482

483

485

489

492

493

as opposed to those formed without incorporating weights. Moreover, a comprehensive analysis of the features utilized in the clustering analysis has revealed the degree of correlation and importance of each feature in assessing an institution's performance.

Finally, several clustering experiments have been performed to provide a diverse and nuanced perspective on the data and uncover interesting patterns and structures that may not be evident through a single method. Overall, creating a hierarchical ranking that ranks universities from best to least or relying on a narrow set of indicators to assess an institution's performance may restrict the richness of results. Alternatively, leveraging clustering methods allows us to overcome these limitations and achieve a more nuanced understanding.
